

Introduction

This app is a therapist scheduler website. It features a login and registration page, and dashboards for the adult & underage patients, as well as the therapists themselves.

New users will have the option to register from the login page, and login with the newly created credentials using a username and password.

Existing users can use existing credentials for the same function.

Therapists can set availabilities for which patients can request appointments on their respective dashboards.

System Overview

This program uses MySQL as its main database, flask for the backend, and react for the frontend.

As a system administrator, you would have access to the database with the ability to run SQL commands to it.

To be able to use flask, you need at least Python 3.9, but it's highly encouraged to download the latest version of Python.

Along with python, a virtual environment is highly encouraged to be able to download the required packages.

You must also have MySQL installed to be able to run your own database locally. You should match the names of the database, user and password to the .env file provided in the backend.

Lastly, get the latest version of Node.js and React.

The website is very lightweight, so any functioning computer can realistically run this if the downloaded versions for python, virtual environment, and more match the operating system that the computer is using.

Administrative Procedures

1. Download and install MySQL Community Server on mysql.com
2. Go through the setup (remember the password you chose for root).
3. Download the contents inside the GitHub repository.
 - a. <https://github.com/wy80818/CS447-Project-Repository>
4. Download and install the latest versions of Python and Node.js.
(You might need to restart your computer if the command cannot be found after installation.)
5. In the backend directory, create the virtual environment, enter it, and install the packages listed in requirements.txt. On Windows, it would look something like this:
 - a. `python -m venv venv`
 - b. `venv\Scripts\activate`
 - c. `pip install -r requirements.txt`
6. Afterwards, you can run the backend with:
 - a. `python app.py`
7. In the frontend (in another terminal), install react-calendar and @react-google-maps/api
 - a. `npm install react-calendar`
 - b. `npm install @react-google-maps/api`
8. Then, run the frontend with:
 - a. `npm start`

Any user can create any type of account available on the website on their own.

If you want a fresh start, you can just drop the database in your MySQL terminal, and then simply go to the main menu of the website and select the option between a blank database or one with dummy data.

Troubleshooting

If either the frontend or backend cannot be run, check if you have the required packages installed (requirements.txt and react-calendar respectively). Also, make sure all files are present from the original GitHub repository.

On the website, if there is a server response error, most likely there is an issue with the backend. The exact cause for the error will appear in the terminal for which the backend is running in.
